Abstract:	Deference within a dyad occurs when one partner acknowledges that the other is entitled to some privileges. Although deference is a well-known consequence of relationships between partners of unequal status, little is known on whether deference in one domain can affect interactions between the same actors in the other domains. This can happen within multiplex relationships, especially when they involve firms that have both business and personal interactions between their key decision makers. We combine insights from the literatures on status, multiplex relationships and competitive positioning to examine how actors' behaviors in a business domain of a multiplex relationship are shaped by the deference norms in a personal domain of the same relationship. We argue that marriages between owner-families of Korean business groups cause deferential behaviors between these families as a function of gender-based status differences within kinship ties. We show empirically that the inter-personal deference resulting from marriage affects business group market entries or exits, and in turn the group's performance. Thus, we shed light on how deference spillovers represent a novel mechanism through which one partner can extract advantage over another within a multiplex relationship.

We appreciate editorial guidance of Prof. Laszlo Tihanyi and that of the three anonymous AMJ reviewers. We are also grateful for the feedback from the participants of research seminars at the University of Michigan, New York University and the Bocconi University, where we have presented earlier versions of this paper. We would like to especially acknowledge Javier Gimeno's invaluable feedback at various stages of this research project. It received the E. SUN Academic Award granted by the E. SUN Bank.

Unequal Bedfellows: Gender Role-based Deference in Multiplex Ties between Korean Business Groups

Abstract

Deference within a dyad occurs when one partner acknowledges that the other is entitled to some privileges. Although deference is a well-known consequence of relationships between partners of unequal status, little is known on whether deference in one domain can affect interactions between the same actors in the other domains. This can happen within multiplex relationships, especially when they involve firms that have both business and personal interactions between their key decision makers. We combine insights from the literatures on status, multiplex relationships and competitive positioning to examine how actors' behaviors in a business domain of a multiplex relationship are shaped by the deference norms in a personal domain of the same relationship. We argue that marriages between owner-families of Korean business groups cause deferential behaviors between these families as a function of gender-based status differences within kinship ties. We show empirically that the inter-personal deference resulting from marriage affects business group market entries or exits, and in turn the group's performance. Thus, we shed light on how deference spillovers represent a novel mechanism through which one partner can extract advantage over another within a multiplex relationship.

Status can be defined as an actor's relative position in a social hierarchy (Gould, 2002).

Status differences lead to deference in dyads, where deference can be defined as one actor's acknowledgement that the other is entitled to certain privileges. Lower status actors routinely give the higher status actors more benefits than the latter are expected to return (Blau, 1964). Examples of such unequal interactions have been documented in network ties among firms (Castellucci & Ertug, 2010; Podolny, 1993) and individuals (Granovetter, 2005; Podolny & Baron, 1997). For example, lower status investment banks underwriting public offerings defer to the higher status banks because of their prominent position in the underwriting network (Baum, Shipilov, & Rowley, 2003). As a result, lower-status banks are likely to offer advantageous terms to the higher-status counterparts for participating in their offerings (Podolny, 1993).

Most research examines how deference relationships work within a single domain, e.g. a buyer-supplier relationship (Castellucci & Ertug, 2010) or a relationship between suppliers

1
2
3 (Podolny, 1993), and it is not known whether deference could also spill across different relational
4
5 domains. In this paper we explore how deference between actors in personal relationships affects
6
7 these actors' business decisions. This can happen within multiplex relationships, defined as ties in
8
9 which actors share multiple bases for interaction (Kuwabara, Luo, & Sheldon, 2010; Verbrugge,
10
11 1979; Wasserman & Faust, 1994). Multiplex ties often involve firms whose business relationships
12
13 are simultaneously intertwined with the personal relationships of their key decision makers
14
15 (Ingram & Roberts, 2000). Such ties are pervasive around the world. Executives in family firms
16
17 both in developed and emerging economies are frequently also members of owning families who
18
19 are inter-connected through kinship (Ingram & Lifschitz, 2006; Luo & Chung, 2005); likewise
20
21 managers in competing firms are often connected by friendship (Ingram & Roberts, 2000; Ingram
22
23 & Zou, 2008) or college alumni relationships (Wasserman, 2012) which span both business and
24
25 personal domains; and exchange of information and evaluation occurs through multiplex
26
27 relationships connecting managers and stock analysts (Cohen, Frazzini, & Malloy, 2010).
28
29 Spillover of deference in a multiplex tie happens when deference in a personal relationship alters
30
31 the partners' business behaviors.
32
33
34
35
36
37

38
39 Examining status differences among actors and the spillovers of deference across different
40
41 domains of a multiplex tie (Gimeno & Woo, 1996) is valuable because this may affect
42
43 strategically important decisions, such as market positioning or reactions to a competitor's entry
44
45 into a firm's markets (Ingram & Roberts, 2000; Podolny & Scott Morton, 1999). Research on
46
47 competitive positioning traditionally examines how firm market entry or exit behaviors are caused
48
49 by economic drivers such as prior overlap of their market positions or profitability (Korn & Baum,
50
51 1999; Korn & Rock, 2001). Personal interactions between the key decision makers, and especially
52
53 their deference relationships, may also influence the pattern of market entries and exits of their
54
55 companies, yet how these spillovers occur remains unexplored in management research.
56
57
58
59
60

1
2
3 In this study, we examine market entry and exit behavior of Korean business groups
4 (chaebol) connected by marriage relationships between their owner families. Such marriage
5 relationships represent multiplex ties that comprise both personal and business domains as bases
6 for interaction. The business domain comprises a direct channel for information exchange
7 between trusted business partners (i.e., owner families), which among other things involves the
8 exchange of insights about chaebols' strategic positions in individual markets. The personal
9 domain is the kinship relationship between the business owners' families that involves "husband"
10 and "wife" roles of different family members. The husband/wife interactions are deeply
11 embedded within the Confucian cultural tradition, which clearly spells out the roles and
12 expectations about the appropriate behaviors for spouses and their families. We show that gender
13 and family roles in a marriage tie, as prescribed by the Confucian tradition, affect business
14 decisions of their chaebols in terms of entries to or exits from common markets.

26
27
28
29
30

31 Specifically, we propose that families in both chaebols will exchange information about
32 markets in which their companies are involved. Had there been no clear deference relationship
33 between the two families, both parties would have acted upon this information and reconfigured
34 their market positions through market entries and exits in a similar fashion. Chaebols would do
35 that in the expectation of benefits from the redeployment of resources and capabilities between
36 different markets over time (Helfat & Eisenhardt, 2004). Yet, because this multiplex tie also
37 involves personal interactions between the families of the husband and wife, which are governed
38 by the Confucian tradition that gives privileges to the husband and his family, it will be the
39 chaebol of the husband that takes advantage of this information and actively reconfigures its
40 strategic position through entries to or exits from the common markets. By contrast, the wife's
41 chaebol will restrain its market entry or exit behaviors and just accommodate those of the
42 husband's chaebol. This study makes contributions to the literatures on multiplexity (Shipilov,

7 8 **THEORY**

9 10 11 12 **Status, Deference and Multiplexity**

13
14
15 There are different explanations for the origins of inequality in social systems that lead to
16
17 situations in which some groups have better opportunities than the others (Blau, 1964). A market-
18
19 based explanation suggests that some actors are at the top of the hierarchy because of their
20
21 superior skills (Homans, 1961). Another view suggests that inequality is best explained through
22
23 the existence of an enacted social order in which powerful individuals or social groups have
24
25 hegemony over social positions that generate rents (Sørensen, 1996). Gould (2002:1147)
26
27 synthesizes the two views and suggests that inequality can be explained by the notion of status,
28
29 i.e., “the prestige accorded to individuals because of the abstract positions they occupy rather than
30
31 of their immediately observable behavior.” According to this framework, economic actors have
32
33 some underlying qualities (e.g., superior skills) that allow them to attain a higher social position,
34
35 which then increases the returns on these qualities. Regardless of the origins of inequality,
36
37 individuals at the bottom of the social system show deference to the individuals at the top, which
38
39 manifests itself in the former’s willingness to accept worse terms of exchange for the privilege of
40
41 associating with the latter (Castellucci & Ertug, 2010), and these continued acts of deference
42
43 perpetuate the inequality.
44
45
46
47
48
49

50
51 Deference in personal relationships matters for individual outcomes such as earnings and
52
53 job opportunities (e.g. Blau, 1964), but it can also matter for business outcomes when the persons
54
55 who exhibit deference also make important business decisions, such as whether to enter a new
56
57 market or how to react to a new entrant. Podolny and Scott Morton (1999) examine how members
58
59
60

1
2
3 of British shipping cartels in the 19th century reacted to the entries of competitors into their
4
5 markets. Despite the reduction in the market profitability with an increase in competition,
6
7 incumbents deferred to the new entrants of high status (e.g., when the owner of the shipping firm
8
9 was a Knight) by accommodating their entries and avoiding price wars. By contrast, incumbents
10
11 tried to prevent the entry of low status competitors through vigorous price wars. The reason for
12
13 this unequal treatment was that shipping-firm owners of high status were judged to be more likely
14
15 to uphold the norms of the cartel, and hence could be trusted not to cheat or attempt renegotiation
16
17 of cartel agreements. Thus, assessment of an interpersonal status ranking and the resulting
18
19 difference was transferred into the firm behavior of accommodating entry or starting a price war.
20
21 While one can argue that deference based on personal status could be the thing of the past, in this
22
23 paper we are interested in observing whether deference in personal relationships can affect
24
25 business decisions in more contemporary settings and, if found, what such deference patterns can
26
27 tell us about social embeddedness of economic action—such as market entries and exits—more
28
29 broadly.
30
31
32
33
34
35

36 The underlying qualities that allow individuals to claim a higher status position can have
37
38 either internal or external sources of value (Zelditch Jr & Walker, 1984). The internal source is
39
40 driven by the value of the underlying qualities, while the external source of value is driven by
41
42 social norms. In working groups, for example, the internal source of value can come from the
43
44 group's shared understanding that a certain skill (i.e., knowledge of math) is necessary to create a
45
46 successful output (e.g., complex financial derivative product); and individuals with such skills can
47
48 obtain a high status position specific to the focal working group (Ridgeway & Berger, 1986).
49
50

51 The external source of value derives from norms that dictate what the actors' roles are,
52
53 and is generalizable beyond specific workgroups to the broader society. These norms often come
54
55 from the national culture. In turn, culture includes a set of shared beliefs and norms held by the
56
57
58
59
60

1
2
3 members in a society, which is communicated through socialization processes (Schein, 1990).
4
5 Cultural influence can be a major source of deferential behavior within the dyad whereby a
6
7 position (e.g., a title or a role) occupied by one actor requires the acceptance that the other actor,
8
9 occupying a different social position, is entitled to certain privileges irrespective of the actor's
10
11 skills. Cultural influences are absent from most organizational studies of status because these
12
13 studies are predominantly executed at the level of the inter-firm networks, where the effect of
14
15 national culture is either held constant or is so ambiguous that it is not clear which organization
16
17 would benefit from the cultural norms (e.g. Podolny, 1993; Shipilov et al., 2011). Instead, scholars
18
19 of status assume that deference is solely derived from the pattern of affiliations: the more
20
21 relationships to high status individuals the focal individual has, the higher is the status of the focal
22
23 individual (Podolny, 1993) to whom the lower status others have to defer (Castellucci & Ertug,
24
25 2010). However, cultural influences represent decidedly non-network based sources of deference
26
27 that available research tends to overlook. The fact that a Knighted person is entitled to privilege
28
29 that spills over from a personal domain to a business domain is a cultural factor not based on this
30
31 person's social ties or skills, but rather on the external source of value that is ascribed to this
32
33 person's social position (Podolny & Scott Morton, 1999).
34
35
36
37
38
39

40
41 Examination of culture as a source of deference is important because cultural effects have
42
43 both a broad set of sources and highly general reach. Culture affects the direction of personal
44
45 deference relationships in many contexts, for example individuals from lower castes in India defer
46
47 to individuals from the higher castes (Chen, Chittoor, & Vissa, 2015) while women tend to defer
48
49 to men in the Asian societies (Greenhalgh, 1985; Lee, Parish, & Willis, 1994). Thus, at least in
50
51 traditional societies, differences between individuals based on different castes or gender can lead
52
53 to clearly defined hierarchical patterns of dyadic relationships that have nothing to do with their
54
55 network positions. Economic impact of culture has also been linked to broader religious and
56
57
58
59
60

1
2
3 philosophical systems such as claims of protestant ethic being a good match to capitalism (Weber,
4 1904) and Muslim restrictions on lending practices affecting economic growth (Kuran, 2004).
5
6

7
8 Recent resurgence of interest in multiplex relationships – ties that are comprised of
9
10 multiple bases of interaction (Kuwabara et al., 2010; Verbrugge, 1979; Wasserman & Faust, 1994)
11
12 – can provide a fruitful opportunity to reexamine the role of national culture as a source of
13
14 deference within dyads. Multiplexity is relevant to our argument when it amounts to the existence
15
16 of a personal relationship between key decision makers in different organizations, which then
17
18 could affect collaborative behaviors of these organizations in a business domain. There are two
19
20 cases in which one can think about multiplexity. First, multiplexity can arise when two actors are
21
22 connected through different types of ties such that each tie offers them different bases for
23
24 interaction. For example, two CEOs of different investment banks could be members of the same
25
26 alumni association, which allows them to interact as acquaintances in an informal setting. At the
27
28 same time, they could work together on a deal to underwrite a public offering for a common client.
29
30
31 Second, the two organizations could be connected through a single relationship in which its
32
33 members have different bases for interaction. For example, two business groups could be
34
35 connected by marriage between their owner-families. In this case, a marriage tie connects
36
37 individuals who are related through personal kinship, yet these individuals are also involved in
38
39 running businesses that could collaborate in different markets even without creating formal
40
41 arrangements such as strategic alliances or joint ventures. These two cases are similar in that they
42
43 involve relationships that form different bases of interactions—one in a personal domain and
44
45 another in a business domain. These cases differ in that the first involves the formation of two
46
47 types of ties, whereas the second involves the formation of a single type of tie. Yet, the number of
48
49 ties between companies is not going to be as consequential for studying the impact of deference in
50
51 personal ties on organizational outcomes. Rather, this effect will occur when a personal
52
53
54
55
56
57
58
59
60

1
2
3 relationship involves individuals who are either the decision-makers for the business or who are
4
5 so close to them that they affect information exchange and business decisions¹.
6
7

8 Available research tends to think about multiplexity as desirable, because it stabilizes
9
10 exchange and creates trust and interdependences between partners. Rogan (2014) has shown that
11
12 multiplex relationships between the advertising agencies and their clients have a low likelihood of
13
14 dissolution. Multiplexity helps maintain client-agency relationships even if one of the executives
15
16 who built those relationships in the first place leaves the firm. Uzzi and Gillespie (1999) find that
17
18 the clients obtained capital at the lower cost from the bank if they had a multiplex relationship.
19
20 When two organizations are connected by an alliance and a board interlock, multiplexity helps
21
22 facilitate mutual learning from partnering experience (Beckman & Haunschild, 2002).
23
24
25
26

27 Despite these benefits, multiplex ties could have significant costs that the literature tends
28
29 to overlook. When senior decision makers acknowledge the existence of a status hierarchy and
30
31 show deference to some partners in a one domain of a multiplex relationship, this can affect their
32
33 decisions in the other domain, which can put one partner at a disadvantage over another. For
34
35 instance, Ingram and Lifschitz (2006) demonstrated that kinship between shipbuilders reduced the
36
37 failure rates of their companies, yet they did not explore the possibility that individuals occupied
38
39 unequal roles in the kinship relationships (e.g. a patriarch of a family vs. a distant cousin; a
40
41 relative who is a Knight vs. a relative who is a commoner), producing an inequality that could
42
43 result in deference relationships spilling over into the business domain. Specifically, businesses
44
45 run by the family patriarch may have more flexibility than businesses ran by the lesser kin. Even
46
47 beyond cultural influences, deference could come from the unequal distribution of status in one
48
49
50
51
52

53
54 ¹ In contrast to a multiplex relationship, a “uniplex” relationship would involve a single basis for interaction between
55 the actors. For example, two companies can be connected either by a strategic alliance or by board interlock
56 (Beckman & Haunschild, 2002). Alternatively, two individuals can be relatives but not collaborate in business
57 (Ingram & Lifschitz, 2006) or work for alliance partners yet not share any personal relationships.
58
59
60

1
2
3 domain of a multiplex relationship and still affect another domain. For example, two companies
4
5 connected by a board interlock may have a high status board member who clearly favors the
6
7 interests of one company over another. As the other board members defer to this person, these
8
9 influences can spill over to their strategic alliance where partner favored by the high status board
10
11 member will be given the leading role over the other, less favored, partner. Thus, multiplex ties
12
13 can contain “Trojan horses”: relationships with clear deference patterns in one domain that could
14
15 hijack the partners’ behaviors in the other domains (Gimeno & Woo, 1996).
16
17
18

19
20 In the sections that follow, we examine how deference can spill over across different
21
22 domains of a multiplex relationship, making business decisions between otherwise equal partners
23
24 subject to hierarchies within personal relationships. Our specific conjecture is that deference in
25
26 roles among the individuals in a personal domain of a multiplex tie can manifest itself in
27
28 asymmetry of business strategies adopted by the businesses owned by these individuals’ family
29
30 members. Thus, interpersonal deference based on culturally induced status hierarchies affects the
31
32 interactions in the business domain.
33
34
35
36

37 **Business Consequences of Personal Deference in Korea**

38
39 Our context is marriage ties between owner families of business groups in Korea. This
40
41 context is a perfect laboratory to examine how cultural influences in a personal domain of a
42
43 multiplex tie can create asymmetry in its business domain because of the Confucian norms that
44
45 strictly guide personal relationships, which then affect how these groups behave within their
46
47 business relationship. Marriages between business families have been historically important
48
49 drivers of information exchange, coordination, and trust among economic actors (Granovetter,
50
51 1995). They have been documented as early as Florentine Europe (Padgett & Ansell, 1993); in
52
53 modern data they have been shown to secure long term inter-group collaboration (Kerbo &
54
55
56
57
58
59
60

1
2
3 McKinstry, 1995) and exchange of product knowledge, coordinated bidding, and pricing (Ingram
4 & Lifschitz, 2006). Nowadays, kinship networks are closely integrated with business groups
5 around the world, which help enterprises overcome weakly developed judicial and business
6 systems (Khanna & Rivkin, 2001; Manikandan & Ramachandran, 2015).
7
8
9
10
11

12 The hierarchy in the family relationships in Korea follows a strict pattern that is prescribed
13 by the traditional Confucian value system and directs deference in personal relationships.
14

15 Confucian culture emphasizes strong bonds of loyalty to family members (Omohundro, 1982;
16 Redding, 1990), and promotes a dutiful responsibility to seniors (Greenhalgh, 1985; Hamilton,
17 1985). A key feature of Confucian culture is the asymmetry in gender roles that puts males in a
18 privileged position. A son is responsible for taking care of his parents, and he inherits the parents'
19 wealth and social status. A daughter is exempt from the duty of caring for her original family, but
20 she is also deprived of property rights (Greenhalgh, 1985). In other words, sons are entitled to be
21 descendants of the family (Greenhalgh, 1985; Lee et al., 1994) whereas daughters have to re-build
22 own identity and economic resources through marriage and fully integrate into a husband's family.
23
24
25
26
27
28
29
30
31
32
33
34
35

36 The deference in personal relationships will matter when it affects business outcomes, for
37 instance, when marriage involves members of the families that own companies, most notably
38 business groups (chaebol). In order to understand how behaviors of these groups in business can
39 be affected by deference in personal relationships, it is important to first consider the principal
40 drivers of these groups' success. These groups optimize their use of resources, skills, or customer
41 bases across markets (Rumelt, 1974). Member companies can leave some markets and redeploy
42 their resources and skills or target customers in what they think are the more promising markets.
43 Such behaviors are observed when companies look for inter-temporal economies of scope, i.e. the
44 synergies that arise from reallocating resources across different markets (Helfat & Eisenhardt,
45 2004). If we can show that such market entry and exit behaviors are collaborative in nature and
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 are shaped by deference in the marriage relationships involving the groups' owner-family
4
5 members, then we have demonstrated that deference in personal relationships can affect business
6
7 outcomes.
8
9

10 Business groups provide three critical inputs to their affiliates which can be transferred
11
12 across markets, even when these markets are unrelated. These inputs are finance, technology and
13
14 management talent. First, chaebols provide their affiliates with access to capital. Given capital
15
16 market imperfections, chaebols mostly fund their operations through retained earnings or debt, as
17
18 opposed to outside equity. By exiting one market, a chaebol can free up the retained earnings,
19
20 debt carrying capacity, or simply available cash flows, which it can then use to enter another
21
22 market. Second, chaebols offer technology development services to their affiliates. They do so by
23
24 integrating R&D centers along very broadly defined lines, such as electronics, infrastructure or
25
26 automotive, which can provide shared services to both related and unrelated businesses. Third,
27
28 chaebols provide talent management services, including managerial and technical training to their
29
30 workers, which compensate for scarcity of talented managers and engineers. Consequently, in
31
32 addition to reallocating financial resources, a business group can also reallocate shared R&D
33
34 capacity and talent by exiting one market and entering another (Chang & Hong, 2000; Khanna &
35
36 Palepu, 1997).
37
38
39
40
41
42

43 Yet, the transfer of resources will be associated with significant adjustment costs. The
44
45 direct costs involve moving these resources from one market to another. Indirect costs involve
46
47 disruption of business in the market which the focal firm is trying to exit as well as the costs
48
49 associated with operating below the optimal capacity both in the new market and in the market
50
51 that the firm is in the process of exiting (Helfat & Eisenhardt, 2004). When a firm enters a new
52
53 market, it needs to learn how to compete in that market, who the key customers or suppliers are,
54
55 and how to deal with government regulation (Day & Montgomery, 1983). Furthermore,
56
57
58
59
60

1
2
3 incumbent competitors may launch preemptive attacks on the newly established positions of the
4 focal firm in order to dissuade it from expanding its presence in the focal market (Fudenberg &
5 Tirole, 1986; Kreps & Wilson, 1982). Such competitive attacks could amount to significant
6 below-cost pricing from the incumbent competitors' affiliates, which can compensate for the
7 losses through cross-subsidization and low transfer prices from the other affiliates of the
8 competing chaebol (Chang & Hong, 2000). Costs specifically related to exits occur because
9 competitors that remain in the market that the focal chaebol is planning to exit can attack the
10 weakened position of the affiliate, which has already transferred some of its resources (e.g. cash,
11 talent) to the new market, thus lowering the value of the assets which the focal firm can sell and
12 reducing the value of additional resources that the focal firm can transfer into the new market.
13
14
15
16
17
18
19
20
21
22
23
24
25
26

27 Social relationships often influence the structure of competition in a given market (Dyer &
28 Singh, 1998; Zaheer, Gulati, & Nohria, 2000) as well as a firm's decisions to configure market
29 presence (Jensen, 2003; Rider, 2012). A trusted partner in a market will reduce the firm's
30 adjustment costs both for entry and for exit. The formation of a marriage tie opens a reliable
31 communication channel between two business groups. As the owner families exchange
32 information about the markets in which they are operating, they learn about potential benefits of
33 redeploying resources across different markets with mutual support.
34
35
36
37
38
39
40
41
42

43 In principle, both groups related by marriage should benefit from such mutual support.
44 However, given the asymmetric roles in the newlywed family between the husband and the wife,
45 the husband's chaebol will be allowed to actively reconfigure its position through increased entry
46 to or exit from the common markets; whereas the wife's chaebol will support the market entry or
47 exit activities of the husband's chaebol and will remain passive in its own market position. These
48 behaviors can be explained by the fact that in the Confucian tradition, the husband's family
49 extends a "favor" to the wife's family by selecting her as a bride. This is considered to be a favor
50
51
52
53
54
55
56
57
58
59
60

1
2
3 in the Confucian tradition because, as noted earlier, the daughter is not required to take care of her
4
5 parents' family in the old age and thus doesn't inherit the family's assets. The bride' family (in
6
7 this case the owner-CEO of the wife's chaebol) must repay this favor, which in the context of
8
9 inter-chaebol interactions means supporting the husband's chaebol. In essence, helping in the
10
11 markets to which the husband's chaebol is planning to enter or exit represents a form of informal
12
13 "dowry" that is payable from the wife's to the husband's chaebol, even though both the husband
14
15 and wife are normally too junior to have authority in their chaebol at the time of marriage.
16
17
18

19
20 The adjustments in business strategy following this relation can be either the result of
21
22 informal information exchange and norms, or more explicit agreement. The two owner families
23
24 may develop an informal plan for the husband's chaebol market position re-configuration. The
25
26 wife's chaebol would provide information to the husband's chaebol about potential market
27
28 expansion opportunities, which includes insights into the most attractive markets in which the
29
30 wife's chaebol is operating as well as the identities of the most reliable customers and suppliers in
31
32 those markets. The wife's chaebol can also pledge not to attack the husband's chaebol after it
33
34 enters into its markets, it can answer favorably to an informal request for no attack, or the
35
36 husband's chaebol may simply expect peaceful entry as a result of the family norms related to the
37
38 wife family's obligations. Given any of these insights and help, the husband's chaebol is able to
39
40 increase its propensity to enter the markets of the wife's chaebol in which the former has no prior
41
42 presence. More specifically:
43
44
45
46
47

48 *Hypothesis 1a: After marriage, a business group owned by a husband's family increases*
49
50 *the probability of entering the markets occupied by the business group which is owned by a wife's*
51
52 *family.*
53
54

55 In order to enter more promising markets, the husband's chaebol might need to free up
56
57 resources from the markets in which it is currently operating. The wife family's chaebol may
58
59
60

1
2
3 provide support facilitating the exit, when it already has operations in one or more markets in
4
5 which the husband's chaebol seeks to leave. Again, this assistance could be the result of the
6
7 owner families of the husband's and the wife's chaebols either developing an exit plan, or
8
9 engaging in the less formal coordinating actions. When both chaebols find themselves in common
10
11 markets and the husband's chaebol sets its sights to redeploying resources elsewhere, the
12
13 husband's chaebol may approach the wife's chaebol for help by purchasing its assets (e.g.
14
15 factories, distribution networks, buildings or the like). Importantly, the husband's chaebol does
16
17 not have to sell off failing businesses; it can also sell well performing businesses to the wife's
18
19 chaebol that is already present in these markets, yet at a price sufficiently high to cover the
20
21 husband chaebol's costs of resource reallocation across markets. The husband's chaebol exit can
22
23 also be facilitated by other means such as the wife's chaebol pledging not to join other firms
24
25 seeking to prey on the weakened husband chaebol during the exit, which enables the husband's
26
27 chaebol to redeploy its resources across markets at a lower cost. Hence, we propose the following:
28
29
30
31
32

33
34 *Hypothesis 1b: After marriage, a business group owned by a husband's family increases*
35
36 *the probability of exiting the markets occupied by the business group which is owned by a wife's*
37
38 *family.*
39

40
41 Finally, the "dowry" will manifest itself in the decreased propensity of the wife's chaebol
42
43 to reconfigure its own market positions vis-à-vis the husband's chaebol. While the wife's chaebol
44
45 will accommodate the entry of the husband's chaebol in its markets, despite the fact that this
46
47 reduces the value that the wife's chaebol can capture there, the wife's chaebol will refrain from
48
49 entering the husband's markets in order to avoid reducing the value that the latter can extract from
50
51 its own markets. Yet, the wife's chaebol will also refrain from exiting the markets in which the
52
53 husband's chaebol is still present in order not to deprive the husband's chaebol of a friendly
54
55 competitor with whom it can cooperate. This can create benefits either from the tacit norms of
56
57
58
59
60

1
2
3 cooperation between the inter-married chaebols or from explicit collusion between them. The two
4
5 chaebols can agree to work together for attacking other (unrelated) competitors in the common
6
7 markets, the wife's chaebol might promise not to join forces with the competitors to attack the
8
9 husband's chaebol, or the two chaebols can agree to collude against customers or suppliers. The
10
11 reduced probability of a wife's chaebol entry into the markets of the husband's chaebol coupled
12
13 with reduced probability of exit from the common markets implies that the wife's chaebol doesn't
14
15 want to create *new* competition for the husband's chaebol, but agrees to collude with it in the
16
17 markets where both of them are already present. Hence, we propose the following hypotheses:
18
19
20

21
22 *Hypothesis 2a: After marriage, a business group owned by a wife's family decreases the*
23
24 *probability of entering the markets occupied by the business group which is owned by a*
25
26 *husband's family.*
27

28
29 *Hypothesis 2b: After marriage, a business group owned by a wife's family decreases the*
30
31 *probability of exiting the markets occupied by the business group which is owned by a husband's*
32
33 *family.*
34

35
36
37 Many Korean executives, whom we interviewed, offered qualitative evidence in support
38
39 of our hypotheses. They recognized that marriage ties among the business groups were important
40
41 sources of coordinating business activities. One interviewee suggested that "*kinship and*
42
43 *marriages between owner-families are the strongest relationships between chaebols one can think*
44
45 *of.*" We also learned that chaebols took asymmetric actions as a result of marriage relationships.
46
47 Another executive recalled: "*when two families that owned chemical companies intermarried in*
48
49 *1990s, they stopped aggressive competition against each other in the chemical business. After the*
50
51 *marriage, I've seen that the husband's chaebol reconfigured its presence in chemicals' markets*
52
53 *whereas the wife's chaebol supported this behavior without changing its competitive position.*
54
55
56
57
58
59
60

1
2
3 *This is a normal courtesy behavior between the in-laws.*” Another interviewee reflected on the
4
5 multiplex nature of the personal/business relationship: *“For owner-families, marriage is a*
6
7 *complex relationship containing both economic and social considerations. The wife’s chaebols*
8
9 *always give away, or at least avoid stirring a male chaebol’s emotion, by entering the in-laws’*
10
11 *markets...If in-law families have some conflicts, the odds are always against the wife because she*
12
13 *becomes a part of the husband’s family. That’s why even when a wife’s chaebol sees some*
14
15 *potential economic benefits from marriage [i.e. through the opportunity to enter new markets],*
16
17 *they hesitate to exploit it. They put more weight on moral costs and reputation in Korean society*
18
19 *and on the well-being of their daughter in the husband’s family than on the exploitation of*
20
21 *immediate business interests.”* Hence, it is plausible that marriages can influence chaebols market
22
23 entry and exit behaviors. We now turn to the quantitative testing of our arguments.
24
25
26
27
28
29
30

31 **METHODOLOGY**

32
33
34 We collected data on the composition of owner families of the largest 60 Korean chaebols
35
36 between 1987 and 2011. Data on intermarriage came from the book *Chaebol-Ga*, where chaebol
37
38 families and their marriage networks are tracked by Seoul News Corporation. We updated,
39
40 validated, and supplemented this information with searches in daily newspapers, business
41
42 magazines and web archives. We also collected data on the chaebols’ presence in different
43
44 industry markets in the same period from the Korean Information Service (KIS) , the biggest
45
46 credit rating agency in Korea. We operationalized the presence of a chaebol in particular industry
47
48 market as the existence of at least one affiliate company in an industry’s 4-digit SIC code. We
49
50 supplemented KIS data with companies’ annual reports and press releases, as well as with data
51
52 available from the Federation of Korean Industries.
53
54
55
56
57
58
59
60

1
2
3 To collect background information on the relationships between chaebols in general and
4 their marriage interactions in particular, we interviewed the three journalists who authored the
5 *Chaebol-ga* book (Seoul News Corporation, 2005). We also did 15 interviews with 10 business
6 executives between 2011 and 2015. The subjects were senior managers with extensive experience
7 of working with the owner-CEOs of the chaebols, and they were familiar with social dynamics
8 surrounding social ties between owner families and their market entry and exit behaviors. The
9 interviews lasted on average 90 minutes and were conducted in person in Korea. The interviews
10 were conducted in Korean, and the quotes we give above are translations.

24 **Data Structure and Empirical Strategy**

25
26 Because we are interested in examining the consequences of marriages on the probability
27 of one chaebol to enter or exit markets in which the other chaebol might be present, we used the
28 event study methodology. Our units of analysis were dyad-market-year observations: we are
29 interested in the presence of two chaebols in particular markets (defined at the level of 4 digit
30 Korean Standard Industrial Classification (SIC) codes) which we tracked +/- 3 years around the
31 marriage events. Each observation can be denoted as *ijmt* or *jimt* where (i) and (j) are the IDs of
32 the chaebols who could enter or exit each other's markets, (m) is the ID of the specific market and
33 (t) is the time when this market entry or exit could happen. The three-year cut off points around
34 the marriage event have contextual significance. The pre-marriage courtship period in Korea is on
35 average one to two years (Kim & Lee, 2003), thus by looking at the three years prior to the
36 marriage we can accommodate the gradual build-up of trust between families throughout the
37 courtship period, as well as capture the dyad before the courtship even began. The three years
38 after the marriage is sufficiently long to reflect the duration of administrative paperwork that
39 needs to be done in Korea to open a new subsidiary (MaellKyungJe, 1996). There were 23

52
53
54
55
56
57
58
59
60

1
2
3 marriages among 60 chaebols during our observation period.

4
5 Our hypotheses are tested in four related datasets: two built around market entries and two
6 built around market exits. All datasets are constructed as treatment/control samples in which the
7 treatment sample takes all available data from the intermarried chaebols, while the control sample
8 takes available dyad-market-year observations involving one married and all other non-married
9 chaebols (i.e. the chaebols that were active in a given year and to which the member of the
10 chaebol which got married could have extended, but did not extend, a marriage tie).

11
12 To study the determinants of market entry of chaebol (i) into a market (m) of chaebol (j)
13 after marriage that happened at time (t), for example, we identified all markets (based on 4-digit
14 SIC codes) in which any affiliate company of chaebol (j) was present from three years prior to (t-
15 3) to three years after the marriage event took place (t+3). Then we examined whether, in these
16 seven years, the chaebol (i) entered any of these markets. To study the determinants of exits of
17 chaebol (i) from a market (m) of chaebol (j) after marriage that happened at time (t), we identified
18 all markets in which chaebols (i) and (j) were present from three years prior to (t-3) to three years
19 after the marriage event took place (t+3). Then we examined whether chaebol (i) exited any of
20 these markets in a given year. The presence of affiliates of the chaebols (i) and (j) in a specific 4-
21 digit market (m) in a given year (t) was coded as 1 and the absence was coded as 0.

22
23 **Dataset 1:** To test Hypothesis 1a about the entries of husbands' chaebols into the markets
24 of the wives' chaebols, our treatment sample comprised dyad-market-year observations (ijmt) of
25 pairs of chaebols whose children got married within our observation window (at times t-3 and t+3,
26 where t is the year of marriage). This dataset is built around cases where the wife's chaebol is
27 present in the focal markets and a husband's chaebol is not present in these markets prior to
28 marriage, but could enter these markets. The control sample for this dataset comprises dyad-
29 market-year observations (ijmt) of chaebols who did not form marriage relationships within the
30

1
2
3 same time period (from t-3 to t+3).² Dyad-market-year observations in the treatment and control
4
5 samples were distinguished by a dummy variable $Married_{(ij)}$ set to 1 for each dyad-market-year
6
7 observation of chaebols that were involved in a marriage tie between (t-3) and (t+3) and otherwise
8
9 a zero for dyad-market-year observations involving chaebols which did not marry. We also
10
11 constructed a dummy variable $After\ Marriage_{(ijt)}$ to designate dyad-market-year observations in
12
13 the treatment group at (t+1), (t+2) and (t+3) time-periods where (t) is the marriage year. Positive
14
15 effect of the dummy $After\ Marriage_{(ijt)}$ will provide support for H1a. This dataset contained
16
17 77,956 dyad-market-year observations after deletions for missing values on theoretical and
18
19 control variables. We also used dummies $Married_{(ij)}$ and $After\ Marriage_{(ijt)}$ in the other datasets.
20
21
22
23
24
25
26

27 **Dataset 2:** To test Hypothesis 1b about the exits of husbands' chaebols (i) from the
28
29 markets of the wives' chaebols (j), our treatment sample comprised dyad-market-year
30
31 observations (ijmt) of chaebols between the periods of (t-3) and (t+3), whose children got married
32
33 at time (t) and in which the husband's chaebol was at risk of exiting the common markets from
34
35 (t+1) to (t+3). This dataset is built around cases where the wife's chaebol is present in the focal
36
37 markets and a husband's chaebol is also present in these markets prior to marriage, but could exit
38
39 from these markets. The control sample in this dataset comprised dyad-market-year observations
40
41 (ijmt) of chaebols who did not form marriage relationships between (t-3) and (t+3) but in which
42
43 the husband's chaebol was present together with other chaebols. Positive effect of $After$
44
45 $Marriage_{(ijt)}$ in this dataset (controlling for whether the observation belonged to a treatment or a
46
47 control group with $Married_{(ij)}$ variable) will provide support for H1b. This dataset had 12,378
48
49
50
51
52

53 ² Another approach to construct a control sample would have been to randomly select a group of dyad-market-year
54 observations involving chaebols (j) to which chaebol (i) did not form a marriage relationship. However, a priori it
55 was not clear how many random observations we should retain, and even more importantly, it was impossible
56 manually to accurately identify the dyad-market-year observations that would be similar to those in the treatment
57 sample on all of the variables.
58
59
60

1
2
3 dyad-market-year observations.
4

5 **Dataset 3:** To test Hypothesis 2a about the entries of wives' chaebols into the markets (m)
6 of the husbands' chaebols, our treatment sample comprised dyad-market-year observations (jimt)
7 of pairs of chaebols whose children got married within our observation window (at times t-3 and
8 t+3, where t is the year of marriage). This dataset is built around cases where the husband's
9 chaebol is present in the focal markets and a wife's chaebol is not present in these markets prior
10 to marriage, but could enter these markets. The control sample for this dataset comprises dyad-
11 market-year observations (jimt) of chaebols who did not form marriage relationships within the
12 same time period (from t-3 to t+3). This dataset had 58,215 observations.
13
14

15 **Dataset 4:** To test Hypothesis 2b about the exits of wives' chaebols (j) from the markets
16 of the husbands' chaebols (i), our treatment sample comprised dyad-market-year observations
17 (jimt) of chaebols between the periods of (t-3) and (t+3), whose children got married at time (t)
18 and in which the wife's chaebol was at risk of exiting the common markets from (t+1) to (t+3).
19 This dataset is built around cases where the husband's chaebol is present in the focal markets and
20 a wife's chaebol is present in these markets prior to marriage, but could exit from these markets.
21 The control sample comprised dyad-market-year observations (jimt) of chaebols who did not
22 form marriage relationships between (t-3) and (t+3) but in which the wife's chaebol was present
23 together with other chaebols. This dataset had 9,382 observations.
24
25

26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 **Control Variables**

48 Because the matching procedure (outlined below) normally drops many unmatched
49 observations to create a sample of similar observations in the control group as in the treatment
50 group and the number of dropped observations increases rapidly with the number of matched
51 variables, we cannot use too many matching variables. Yet, this is not a problem because models
52
53
54
55
56
57
58
59
60

1
2
3 with similar control and treatment groups don't require as many additional controls as models in
4
5 which control and treatment groups are different. This is because the models with different
6
7 control and treatment groups have much more unobserved heterogeneity that needs to be
8
9 accounted for with extra control variables (Iacus, King, & Porro, 2011).
10
11

12
13 There are several economic drivers of market entry and exit. For example, multimarket
14
15 contact between chaebols could affect their probability of market entry or exit (Korn & Baum,
16
17 1999). To control for these influences, we counted the number of common 4-digit SIC codes in
18
19 which the two chaebols were present. We performed a logarithmic transformation of this variable
20
21 to reduce its skewness. This variable was labelled *Dyadic MMC* (ij) . For each specific dyad (ij)
22
23 this variable did not vary by market, but did vary over time, as the number of common markets
24
25 involving chaebols (i) and (j) can change between (t-3) and (t+3).
26
27
28

29
30 A market that a focal chaebol can enter or exit could be more or less competitive as a
31
32 function of how many other competitors are present in that market. To control for this, we
33
34 constructed a variable *Competition* (ijm) as a count of how many other competitors, not counting
35
36 the partner chaebol, were present in the focal market which the focal chaebol entered or exited.
37
38 This dyadic variable was specific to each individual 4-digit market, thus it varied both by market
39
40 (m) and by time (t).
41
42

43
44 The deference in the relationships between chaebols could also be explained by the
45
46 differences in the breadth of their market presence. A more diversified chaebol might have
47
48 stronger capabilities of managing businesses in multiple markets than a more focused chaebol;
49
50 thus the former may be more likely to successfully search for the inter-temporal scope economies
51
52 than the latter. Chaebols are known to diversify into multiple markets as soon as they had enough
53
54 power to do so (Chang & Hong, 2000), so this measure can also be thought of one of relative
55
56 power: the more markets the chaebol is present in, the more power this chaebol has over a
57
58
59
60

1
2
3 chaebol which is not present in many markets. To control for this, we first computed the total
4
5 number of 4-digit SIC code-based markets in which the chaebols had affiliates and computed the
6
7 logged absolute difference between the counts of the number of markets occupied by chaebols in
8
9 each dyad. We labelled this variable *Specialization Difference*_(ijt).

10
11
12 Chaebols also have different sizes. This was captured by examining the absolute
13
14 differences in the value of their assets. We labelled this variable *Asset Size Difference*_(ijt). These
15
16 business groups could have different debt loads, which could affect their propensity to enter and
17
18 exit markets. To that end, we collected the information on the value of their outstanding debt and
19
20 computed the absolute difference. We labelled the resulting variable *Debt Load Difference*_(ijt).
21
22 Likewise, we also collected information on the absolute difference in the chaebols' total profits
23
24 and computed a variable *Profitability Difference*_(ijt). For each specific dyad (ij), this set of
25
26 variables did not vary by market, but did vary over time within a dyad. All of these variables were
27
28 logged.
29
30
31
32

33
34 Entries and exits can also be affected by the munificence of markets. Unfortunately, we
35
36 did not have data to directly capture the munificence of 4-digit markets, so we resorted to proxies.
37
38 These were variables capturing all chaebols' entry to and exit from the focal markets. That is, as
39
40 all chaebols observe the munificence of each of the 4-digit markets, they should exit less
41
42 munificent markets and enter more munificent markets. Hence, for each year, we computed the
43
44 ratio of how many of the chaebols that were present in the focal market in the past year actually
45
46 exited the focal market. We averaged this ratio over a three year period to smooth annual shocks,
47
48 giving us a control *Exit Ratio*_(mt). In a similar fashion, we computed *Entry Ratio*_(mt) by dividing
49
50 the total number of firms that entered the focal market by the number of firms which are already
51
52 present in that market. Munificent markets will have low exit ratios and high entry ratios.
53
54
55
56

57 In addition to these economic drivers of market entry and exit, there could be other kinds
58
59
60

1
2
3 of relationships between chaebols and other drivers of deference as well. First, we computed the
4
5 total number of formal alliances between each pair of the chaebols. This gave us a variable
6
7 *Alliance Count*_(ijt). Second, we controlled for whether owner-CEOs of two chaebols went to the
8
9 same school, which meant that they belonged to the same-school alumni association, effectively
10
11 creating another informal communication channel between them. This gave us a variable *Same*
12
13 *School*_(ijt). Third, chaebols could have varying levels of power as a function of their political
14
15 connections, which could affect their deference towards each other (Siegel, 2007). To that end,
16
17 we computed how many former government officials worked as CEOs of the chaebols'
18
19 subsidiaries and calculated the absolute difference in these values. This gave us a variable
20
21 *Political Power Difference*_(ijt). We also controlled for the fixed effects of the marriage year.
22
23
24
25
26
27
28
29
30
31

32 **Coarsened Exact Matching**

33
34 Following Aggarwal and Hsu (2014), in our analysis we combined the difference-in-
35
36 differences estimation with Coarsened Exact Matching (CEM) approach. The latter is a
37
38 nonparametric method of preprocessing data, similar to propensity score matching, that allows us
39
40 to construct a treatment sample of dyad-market-year observations that has similar characteristics
41
42 to the control group of dyad-market-year observations in everything except the treatment
43
44 (marriage) itself. The algorithm first creates different strata based on all matching variables, into
45
46 which it classifies observations from the pool of dyad-market-year observations for the treatment
47
48 and control groups. Then, based on these strata, it calculates the weights which should be given to
49
50 each member of the control group based on the similarity of this member to the members of the
51
52 treatment group. If the differences between the member of the treatment group and all the
53
54 members of the control group are too large, the algorithm leaves the observations unmatched and
55
56
57
58
59
60

1
2
3 drops them from the analysis (Iacus et al., 2011). It thus sacrifices statistical power to gain
4
5 robustness against confounding effects of unmeasured differences. The use of CEM reduces
6
7 differences between treatment and control groups that could introduce bias in difference-in-
8
9 differences estimation. The advantage of CEM is that it is able to remove bias (e.g. omitted
10
11 variables, measurement error or reverse causality) related to observed variables on which the
12
13 matching is performed. The CEM procedure allowed us to weight dyad-market-year observations
14
15 in the control and treatment group by their similarity and to exclude those observations that were
16
17 highly dissimilar. This should enable us to estimate regression models on similar samples.
18
19
20
21

22 Because each additional matching variable reduces the sample size, which was a problem
23
24 for smaller datasets, we did not match our data on all possible variables (e.g. Younge, Tong, &
25
26 Fleming, 2015). As we are interested in the relational drivers of market entry and exit behaviors,
27
28 we wanted matching to ensure similarity of treatment and control groups based on the economic
29
30 drivers of market entry and exit (e.g. Greve, 2006; Korn & Baum, 1999) and left relational
31
32 explanations as controls. That is, we initially attempted to match on the *Dyadic MMC*,
33
34 *Competition*, *Specialization Differences*, *Asset Size Differences*, *Debt Load Differences*,
35
36 *Profitability Differences* as well as on market *Entry* and *Exit Ratios*. While matching on all of
37
38 these variables gave us reasonably large samples to work with in Dataset 1 and 2, we faced
39
40 complications in the two other datasets. In Dataset 3 (Wives' Chaebol Entry) CEM on all these
41
42 eight variables only retained observations related to entries to markets of a single partner; whereas
43
44 in Dataset 4 (Wives' Chaebol Exits) CEM did not retain enough observations for the probit
45
46 models to converge. Matching on all eight economic drivers of market entry and exit shrank
47
48 sample sizes in two datasets to unworkable levels, so in these two datasets we performed the
49
50 match on fewer variables. In Dataset 3, we matched on *Dyadic MMC*, *Competition*, *Specialization*
51
52 *Differences*, *Asset Size Differences* and *Profitability Differences* whereas in Dataset 4 we matched
53
54
55
56
57
58
59
60

1
2
3 on *Dyadic MMC, Competition, Specialization Differences, Asset Size Differences, Debt Load*
4
5 *Differences* and *Profitability Differences*. Since the resulting matching weight affects all variables
6
7 describing the focal observation, matching on a subset of variables can still generate control and
8
9 treatment samples that are similar not only on this subset of variables, but also on those variables
10
11 on which we did not explicitly match.
12
13

14 ----- Insert Table 1 about Here -----
15

16
17 Table 1 shows the means of our control variables before and after matching. As can be
18
19 seen in this table, dyad-market-year observations of control and treatment groups were different
20
21 on the economic drivers of market entry and exit prior to matching in all four datasets. For
22
23 example, in Dataset 1 examining the entries of the husbands' chaebols into the markets of wives'
24
25 chaebols, the dyad-market-year observations of the control group (i.e. chaebols that did not form a
26
27 marriage tie) involved pairs of chaebols that had significantly ($p < 0.001$) lower multimarket
28
29 contact with each other (mean $MMC_{(ijt)}$ for the control group was 1.25 whereas it was 1.53 for the
30
31 treatment group). After the application of CEM procedure, the dyad-market-year observations for
32
33 the control group became similar to those in the treatment group for all samples. Interestingly, the
34
35 CEM procedure also selected observations in Datasets 3 and 4 which after weighting were similar
36
37 in control and treatment groups across all eight economic drivers of market entry and exit, despite
38
39 the fact that in Datasets 3 and 4 we matched on some of these variables and not on the others.
40
41 Thus, we preserved sample sizes in Datasets 3 and 4 without sacrificing similarity of control and
42
43 treatment groups based on economic drivers of market entry or exit.³
44
45
46
47
48
49
50

51 RESULTS

52
53
54 ³ The only exception was a variable *Exit Ratio* in Dataset 4 based on which we found marginally significant
55 differences between control and treatment groups (significant at $p < 0.1$ level only), but our results using Dataset 4
56 were identical with or without this variable.
57
58
59
60

1
2
3 Table 2 shows descriptive statistics and correlations of the variables. Panel 2a has
4
5 descriptives and correlations for Dataset 1 (Husbands' Chaebols Entries), Panel 2b has for Dataset
6
7 2 (Husbands' Chaebols Exits), Panel 2c has for Dataset 3 (Wives' Chaebols Entries), and Panel
8
9 2d has for Dataset 4 (Wives' Chaebols Exits). There is no evidence of high correlations between
10
11 any pair of variables, hence collinearity is not an issue in these data.
12
13

14 ----- Insert Table 2 about Here -----
15
16
17

18 Our results are presented in Table 3. We used probit models with clustering of standard
19
20 errors on 4-digit market IDs. This choice was based on the observation that standard errors are
21
22 more reliable with an increase in the number of clusters; and the errors' reliability is questionable
23
24 when the number of clusters is less than 20 (Bertrand, Duflo, & Mullainathan, 2002). An
25
26 alternative approach would be to cluster on the chaebols but this produced substantially fewer
27
28 than 20 clusters in multiple datasets (because the sample has been reduced after matching), and
29
30 thus unreliable standard errors. Clustering on markets produced more than 20 clusters in all
31
32 datasets as can be seen at the bottom of Table 3. The number of observations used in each dataset
33
34 after matching is slightly smaller in Table 3 than what we have in Table 2 (e.g. Table 1 shows that
35
36 we have 2152 matched observations in Dataset 1 but in Table 3 the analyses based on this dataset
37
38 use 1961 observations only), because the probit drops observations if a particular variable (e.g. a
39
40 marriage year fixed effect) predicts either success (DV=1) or failure (DV=0) perfectly.
41
42
43
44
45

46 ----- Insert Table 3 about Here -----
47
48

49 We test Hypothesis 1a in Models 1 and 2 that have the entries of the husbands' chaebols
50
51 into the markets of wives' chaebols as a dependent variable. Model 1 is a baseline, and in Model
52
53 2 we enter the *After Marriage*_(ij) variable. As expected, the coefficient of *After Marriage*_(ij) is
54
55 positive and significant, showing that husbands' chaebols increase the probability of entering the
56
57
58
59
60

1
2
3 markets of wives' chaebols after the marriage. Hypothesis 1b is tested in Models 3 and 4. Model 3
4 is a baseline, while in Model 4 we enter *After Marriage* (*ij*) variable. It is also positive and
5
6 significant, suggesting that after marriages, husbands' chaebols are systematically more likely to
7
8 exit the common markets in which they find themselves together with the wives' chaebols. We
9
10 test Hypothesis 2a in Models 5 and 6 that have the entries of the wives' chaebols into the markets
11
12 of husbands' chaebols as a dependent variable. Model 5 is a baseline, and in Model 6 we enter
13
14 *After Marriage* (*ij*) variable. As expected, the coefficient is negative and significant, showing that
15
16 the wives' chaebols have a lower probability of entering the markets of husbands' chaebols after
17
18 the marriage. Hypothesis 2b is tested in Models 7 and 8. Model 7 is a baseline, while in Model 8
19
20 we enter *After Marriage* (*ij*) variable. It is also negative and significant, showing that after
21
22 marriages, wives' chaebols are systematically less likely to exit the common markets in which
23
24 they find themselves together with the husbands' chaebols.⁴
25
26
27
28
29
30

31
32 Interestingly, *Same School* (*ijt*) was dropped in Models 3-6 whereas *Alliance Count* (*ijt*)
33
34 was dropped in Models 5 and 6. This is because when we matched on the economic drivers of
35
36 market entry and exits, CEM in these specific datasets retained observations that only had zero
37
38 values on these two relational variables. As there was no variation in these variables, they were
39
40 dropped from the probit analysis. In other words, Models 3-6 are estimated on the matched
41
42 sample of firms that did not have owner-CEOs that went to the same school and the Models 4-5
43
44
45

46
47 ⁴ In a supplementary analysis using the matched samples, we also examined whether market attractiveness moderated
48 the effect of marriage by entering interactions between *After Marriage* and *Entry Ratio* to reflect the extent to which
49 the spouse chaebol was present in the attractive (growing) market. The coefficient estimate was positive and
50 significant for husbands' chaebols, but could not be estimated for wives' chaebols because they never entered
51 growing husbands' markets after marriage in the matched sample. We did the same analysis for exits (i.e. constructed
52 interactions *After Marriage* x *Exit Ratio*) and found that the husbands' chaebols increasingly exited unattractive
53 markets of the wives' chaebols that other firms also exited. Finally, we found that the wives' chaebols remained in
54 the unattractive husbands' markets unless there was an extreme exodus of other firms from these markets. This
55 analysis shows that the husbands' chaebols decisions to enter and exit markets are driven by the strategic logic of
56 entering and exiting markets together with the other firms, whereas the wives' chaebols defer to the husbands'
57 chaebols, often against common strategic logic.
58
59
60

1
2
3 are estimated on a matched sample in which firms don't have alliances with one another. This is
4
5 another reason why we did not match on these relational variables to begin with: if there is little
6
7 variation in a particular variable across a large enough sub-sample, this variable is not a great
8
9 candidate on which to do the match. Given that there was more variance on the *Political Power*
10
11 *Difference (ijt)* than in the *Same School (ijt)* and *Alliance Count (ijt)*, in a supplementary analysis
12
13 we added it to the list of matched variables that captured economic drivers of market entry and
14
15 exit, obtained a balanced sample between treatment and control groups, and found that our
16
17 theoretically meaningful results were very similar to those reported above.
18
19
20
21

22 23 **Alternative Clustering Solution**

24
25 As we still were concerned about potential non-independence of observations across
26
27 chaebol dyads, in a supplementary analysis we clustered on chaebol dyad IDs instead of
28
29 clustering on the ID of the market. Clustering on the ID of the chaebol dyad can be appropriate
30
31 because our unit of analysis is a dyad-market-year observation. In the clustering on the dyad, we
32
33 had 27 clusters in the Dataset 1 predicting husbands' chaebols entries, 18 dyad-based clusters in
34
35 Dataset 3 predicting wives' chaebols entries, 26 dyad-based clusters in the Dataset 2 predicting
36
37 husbands' chaebols exits, 42 dyad-based clusters in the Dataset 4 predicting wives' chaebols exits.
38
39 Our probit results reported in Table 4 were the same.
40
41
42
43

44 --Insert Table 4 around here--
45
46

47 48 **Testing for endogeneity**

49
50 If the assignment of observations to control and treatment groups is not random after
51
52 matching, then difference-in-differences estimator can still be biased. To that end, we
53
54 supplemented CEM with augmented Durbin Wu-Hausman (DWH) tests to see whether marriage
55
56 (treatment) was endogenous. To do this test, we needed to identify strong instruments for the first-
57
58
59
60

1
2
3 stage equation in which we would predict the probability of marriage. To achieve this goal, we
4
5 used two sets of instruments. The first set of instruments was based on the *Partner's Father Age*
6
7 as an exogenous variable to predict $Married_{(ij)}$ in the first-stage regression. For the dataset
8
9 examining the market entry and exit of the husbands' chaebols, *Partner's Father Age* was the age
10
11 of the wives' fathers; for the dataset examining the market entry and exit of the wives' chaebols,
12
13 *Partner's Father Age* was coded as the age of the husbands' fathers. This variable was a proxy for
14
15 the average ages of the potential husband or wife, the data on which was not available to us. The
16
17 higher the *Partner's Father Age*, the more eligible children for marriage is this person likely to
18
19 have. For example, if a parent is 30 years old, he is unlikely to have children of marriable age; yet
20
21 a parent of 60 years of age is likely to have several children of marriable age. However, the
22
23 number or the age of children in one chaebol's owner family will have no direct impact on the
24
25 propensity of the *other* partner chaebol to enter or exit specific markets, thus the exclusion
26
27 restriction of *Partner's Father Age* on the dependent variables is satisfied. To allow for the non-
28
29 monotonic effect of this exogenous variable on the probability of marriage—when the partner's
30
31 father is very old, the prospective partner is likely to be older and might have already been
32
33 married—we included both linear and quadratic terms of *Partner's Father Age* into regressions.
34
35

36
37
38
39
40
41 The second set of instruments was based on a count of how many children from the
42
43 partners' family have already been married to non-chaebol partners. Since each owner-CEO is
44
45 likely to have a number of children, after some of these children get married to the other families,
46
47 the probability of subsequent marriages involving the children of the same owner-CEO to other
48
49 chaebols should initially increase (because the owner CEO has “learned” how to marry off their
50
51 children), but then decrease as the number of eligible to marry children in an owner CEO family
52
53 is reduced as many of them have been already married. However, as children captured in this
54
55 variable are married to families outside of the focal chaebol's social circle, then their number
56
57
58
59
60

1
2
3 cannot directly affect the other chaebol's market entries or exits, which satisfies the exclusion
4 restriction. This variable was labelled *Partner's Family Other Marriages*; we computed a linear
5 and a quadratic term for it.
6
7
8

9
10 The augmented Durbin Wu-Hausman test (DWH) involves computing residuals after the
11 first stage regression predicting the endogenous variable (*Marriage*) that includes all of the co-
12 variates used the second stage plus exogenous instruments. These residuals are then included in
13 the second stage regression together with the main effect of the endogenous variable. If residuals
14 are significant in the 2nd stage, then there is endogeneity. In other words, the DWH test is the
15 significance test for the predicted residuals of the endogenous variable in the second stage
16 regression. Of course, for this test to be meaningful, the instruments predicting endogenous
17 variable have to be strong. In other words, they have to have high F-statistics for the first stage
18 regressions (which attests to the strength of the instruments). In the market entry datasets (i.e.
19 Dataset 1 and Dataset 3) as well as in the husband's market exit (Dataset 2) after matching, the
20 linear and quadratic terms for *Partner's Father Age* produced high F-statistics in stage 1
21 regression. In Dataset 4 (capturing the wife's chaebols exits) *Partner's Father Age* did not
22 produce a strong F-statistic, hence we replaced it with a linear and a quadratic term for the
23 *Partner Family Other Marriages*. The resulting F-statistics and the corresponding augmented
24 DWH tests for the specific models are reported at the bottom of Table 3. These results indicate
25 that despite the strength of the instruments, there was no endogeneity in marriage after matching;
26 hence we don't have to use models with instrumental variables for our analyses.

48
49

50 **Economic Effects**

51
52 We assessed economic effects on the changes in the predicted probabilities of market
53 entry and exit. Based on Model 2, for example, we determined that the estimated marginal effect
54 of *After Marriage* was 0.065. The mean probability of market entry before marriage is 0.087 in
55
56
57
58
59
60

1
2
3 Dataset 1, so the formation of a marriage tie increases the probability of a husband's chaebol
4 entering the specific market of a wife's chaebol by ~ 75% (i.e., 0.065/0.087). In Model 4, *After*
5
6
7
8 *Marriage* increases the probability of the husband's chaebol market exit by 0.036. The mean
9
10 probability of market exit before marriage is 0.077 in Dataset 2, so the formation of a marriage tie
11 increases the probability of a husband's chaebol exiting the specific market of a wife's chaebol by
12
13 ~ 50%. Based on the results in Model 6, we determined that the average marginal effect of *After*
14
15
16
17 *Marriage* was -0.016. The mean probability of market entry before marriage is also 0.016 in
18
19 Dataset 3, so the formation of a marriage tie totally freezes the market entry behavior of a wife's
20
21 chaebol in the markets where it overlaps with the husband's chaebol. In Model 8, *After Marriage*
22
23 affects the probability of the wife's chaebol market exit by ~ -0.075. Because the mean
24
25 probability of market exit before marriage is 0.11 in Dataset 4, the formation of a marriage tie
26
27 decreases the probability of a wife's chaebol exiting the specific market of a husband's chaebol
28
29 by 68%. These are all very large effects on chaebol entry and exit behaviors.
30
31
32

33 34 **Seemingly Unrelated Estimation**

35
36 In Table 5 we also examined whether the coefficients for husbands' and wives' chaebols
37
38 entries and exits were significantly different from one another in a seemingly unrelated estimation
39
40 models. This technique combines estimation results – parameter estimates and associated
41
42 covariance matrices – from pairs of regressions, so we can account for possible non-independence
43
44 of entry and exit decisions made by the husbands' and wives' chaebols. The tests for the equality
45
46 of coefficients of *After Marriage* in each pair of models (i.e. Model 1a vs. Model 1b and Model
47
48 2a vs. Model 2b) are rejected ($p < 0.01$), suggesting that wives' chaebols indeed defer to the
49
50 husbands' chaebols by limiting their entries and exits. In the second panel of the table we pool
51
52 analyses based on the entries and exits of the husbands' chaebols separately from those of the
53
54 wife's chaebol. This combines parameter estimates and associated covariance matrices that
55
56
57
58
59
60

1
2
3 involve regressions related to husbands' chaebols market behavior in Model 1a and Model 1b and
4
5 wives' chaebols market behavior in Model 2a and Model 2b. These models could in theory have
6
7 different estimates of the robust standard errors because the combined models have different
8
9 clusters, but we find that our results remain unchanged.
10
11

12
13 --- Insert Table 5 about Here---
14
15
16

17 **Performance Consequences of Entries and Exits**

18
19 Our deference arguments were based on the assumption that husbands' chaebols actually
20
21 benefit -- or at least that believe that they benefit -- from market entries or exits. To test this
22
23 assumption, we collected data on the personal wealth of chaebols' owner CEOs. This data is
24
25 published annually by the Korean government in the form of a ranking with a lower number (i.e.,
26
27 1) illustrating a higher wealth rank of a given person as compared to a higher number (i.e., 30)
28
29 indicating an inferior wealth rank. The wealth of the owner-CEOs is highly linked to the overall
30
31 financial performance of the chaebol, hence it represents a reasonable proxy for the chaebol's
32
33 performance. For this analysis, we use only the chaebol that had marriage events, and we change
34
35 the organization of the data from the dyad-market-year structure to chaebol-year structure in the
36
37 same time period that we performed our main analyses. In addition to the variables which we used
38
39 in the main analysis (e.g. chaebols's *Asset Size*, *Specialization*, *Debt Load*, *Profitability*), we also
40
41 constructed a dummy – *Husband's Chaebol* – to identify whether the focal observation belonged
42
43 to a chaebol which married its son (=1) or daughter (=0). We also counted the number of entries
44
45 to and exits from the markets which the focal chaebol has done in a given year after the marriage.
46
47 As chaebols could enter and exit both the markets of the marriage partners and the other markets,
48
49 we constructed four variables: *Market Entries (Partner)* and *Market Exits (Partner)*, which
50
51 captured the entries to and exits from the marriage partners' markets as well as *Market Entries*
52
53
54
55
56
57
58
59
60

1
2
3 (*Other*) and *Market Exits (Other)* that captured entries and exits of markets which did not involve
4 marriage partners. We took logarithms of these variables.
5
6

7
8 Because the number of alliances in the markets that chaebols have entered differed from
9 the number of alliances in the markets from which chaebols have exited, we computed two
10 variables for this analysis: *Alliances in Entered Markets* and *Alliances in Exited Markets* as the
11 counts of the number of inter-chaebol alliances in the markets that individual chaebols have
12 entered and exited respectively. We also counted separately the school ties that chaebols owner-
13 CEOs had in the markets that their chaebols entered and exited, giving us the variables *School*
14 *Ties in Entered Markets* and *School Ties in Exited Markets*. We also counted the competitors that
15 the focal firm has encountered in the markets that it entered and in the markets from which it
16 exited separately. This yielded the variables *Competition in Entered Markets* and *Competition in*
17 *Exited Markets*. There was very high correlation between competition in entered/exited markets
18 and multimarket contact that the chaebols experienced with each other in these markets, so we did
19 not include MMC-based variables in this analysis. Finally, we averaged entry and exit ratios
20 across all markets that the focal chaebol has entered or exited in a given year to account for the
21 munificence of these markets.

40
41 Table 6 shows performance analysis. These are OLS models with clustering on the
42 chaebol and fixed effects for the focal chaebol and marriage year. We only kept observations
43 related to market entries and exits following year of marriage. Negative interaction between
44 *Husband's Chaebol* and *Market Entries(Partner)* would show that the husbands' chaebols
45 improve their wealth ranking, relative to the wives' chaebols (i.e., they get superior wealth ranks
46 of 1, 2 or 3 vs. inferior ranks of 15 or 30, for example), by entering markets. Negative interaction
47 between *Husband's Chaebol* and *Market Exits(Partner)* would show that the husbands' chaebols
48 improve their wealth ranking, relative to the wives' chaebols, by exiting from markets.

----- Insert Table 6 about Here -----

Model 1 in Table 6 is a baseline. We enter an interaction between *Husband's Chaebol* and *Market Entries* in Model 2 and then an interaction between *Husband's Chaebol* and *Market Exits* in Model 3. The interaction *Husband's Chaebol* and *Market Entries (Partner)* is negative and significant, but the other interaction is not, indicating that husbands' chaebols improve their owner CEOs' wealth ranking through market entries, but not through market exits. Furthermore, the main effect of *Husband's Chaebol* is positive and significant, indicating that CEOs with sons tend to begin as less wealthy than their compatriots with daughters (again, higher values in our DV imply inferior wealth rank), but the "dowry" in the form of improved market access increases the wealth rank of the CEOs of the husbands' chaebols at the expense of the CEOs of the wives' chaebols. Hence, the deference behaviors of chaebols' owner families have clear business consequences for their enterprises through their increased propensity to enter markets. Because the dependent variable is a rank, we also wanted to check the extent to which our results would change if we used non-linear models such as ordered probit. Hence, we estimated an ordered probit in Model 4 and found the same interaction results as those in Model 3.

DISCUSSION AND CONCLUSIONS

This study was motivated by the neglect of research on the role of status in multiplex relationships, especially on how deference between partners - based on their status differences - can spill over across different domains of a multiplex tie. Such spillovers are most likely in the multiplex ties that involve both a personal and a business domain, especially in contexts where one party occupies a position within a personal relationship that forces this person to show deference to another. In a study of market entry and exit behaviors of Korean chaebols, following the formation of a marriage tie, we found that cultural values giving status differences and

1
2
3 obligations from the wife family to the husband family lead to personal deference, which in turn
4
5 influences business behaviors of their related chaebols. Specifically, the chaebol owned by the
6
7 husband's family is much more likely to enter and exit common markets, as compared to the
8
9 chaebol owned by the wife's family. These results underscore the important role of cultural
10
11 understanding and norms, of which gender inequality is just one example, as a source of
12
13 deference spillovers within multiplex relationships.
14
15

16
17 Our main contributions are to the literatures on multiplexity and competitive positioning.
18
19 Although this study is set in the specific context of Confucian culture, its implications go well
20
21 beyond Korea and other Confucian cultures, and can help us understand multiplexity more
22
23 generally. In a recent essay, Shipilov (2012) developed the beginnings of a relational multiplexity
24
25 perspective. It is based on three related premises: "a) organizations are simultaneously embedded
26
27 in different kinds of relationships, b) these relationships are interdependent and c) this
28
29 interdependence influences organizations" (p. 215). Although highly generalizable, this
30
31 perspective lacks specificity on how exactly the interdependence of relationships can influence
32
33 organizations. Our study begins to flesh out a relational multiplexity perspective by zeroing in on
34
35 personal inter-actor deference as a mechanism that influences organizations within a multiplex
36
37 dyad. We suggest that clear patterns of deference in one domain of a multiplex relationship can
38
39 affect behavior of actors in another domain of this relationship. To make our point very clear, we
40
41 do not claim that business groups—the corporate entities—show deference to each other. What we
42
43 are showing instead is that their owner-CEOs' familial deference in the personal domain spills
44
45 over to the business domain by affecting these groups' collaboration in market entry and exit,
46
47 which then favors one group over another.
48
49
50
51
52
53

54
55 We have shown only one type of interdependence within a multiplex tie that involves
56
57 direct spillovers of dependence in one domain to another. However, there could be other types of
58
59
60

1
2
3 interdependence. For instance, one type of interdependence is mediation, where ties in the social
4 domain may be a bottleneck restricting the functions in the business domain. Another type of
5 interdependence could be amplification or attenuation, where ties in the social domain may
6 positively or negatively moderate the effects of economic drivers in the business domain.
7
8
9

10
11
12 An important insight from our study is that our findings point to the dark side of
13 multiplexity. Conventional wisdom suggests that when companies are connected through
14 multiplex relationships of their key decision-makers, these relationships become durable, strong
15 and stable (Uzzi, 1996) as well as enable actors to deepen their understanding of each other and
16 build trustworthy relationships (Beckman & Haunschild, 2002). Scholars suggest that multiplex
17 ties confer competitive advantages to firms, such as greater ease of knowledge transfer,
18 prevention of client loss (Rogan, 2014), sharing of customers (Ingram & Roberts, 2000), and even
19 increasing the probability of the firms' survival (Ingram & Lifschitz, 2006). While we don't deny
20 these benefits of multiplex ties, our findings suggest that they could also be "Trojan horses"
21 through which a partner could control operations of another within one domain of a multiplex tie
22 by exploiting a deference relationship in another domain of this tie. This point generalizes well
23 beyond Korean business context and marriage ties: a dominant board member (e.g. the person
24 with elite credentials, connections or skills) acting in the interests of one firm inside the board
25 interlock with another firm can elicit deference of other board members from the partner's
26 organization, which in turn can influence the distribution of value that these two firms obtain
27 from their strategic alliance, for example. Failing to account for the multiplex ties between firms
28 and the possibility of deference relationships in these multiplex ties can lead to overlooked factors
29 that affect the behavior and performance of firms connected through these ties.

49
50
51
52
53

54
55 This study also helps understand the determinants of market entry and exit behaviors of
56 companies through a sociological lens. More conventional, organizational economics based
57
58
59
60

1
2
3 explanations, suggest that companies reconfigure their market positions in search of the inter-
4
5 temporal economies of scope (Helfat & Eisenhardt, 2004). This explanation, however, assumes
6
7 that there is no social tie between competitors through which they could explicitly coordinate
8
9 their market entry or exit behaviors (Yu & Cannella, 2013). Our findings imply that – beyond the
10
11 Korean context – competitors frequently have social ties between each other and these ties can
12
13 affect their market entry or exit behaviors by offering a direct communication channel and a
14
15 vehicle for implicit or explicit collusion. Thus, existing models of the origins and consequences of
16
17 market entry and exit should be re-examined by looking at the existence of collaborative
18
19 relationships between competitors, such as their joint ventures, or even personal ties between the
20
21 members of their top management team. Importantly, to affect market entry or exit patterns, the
22
23 social tie connecting competitors doesn't have to be multiplex: all that is required is that the
24
25 companies trust one another sufficiently to exchange information about markets.
26
27
28
29
30

31
32 In our context, the deference interactions within the personal domain of a multiplex tie
33
34 were clearly directional and capable of influencing behavior within this tie's business domain.
35
36 Yet, in the other contexts, different domains of a multiplex tie might involve actor roles that
37
38 generate deference interactions that go in the opposite directions. Specifically, in one domain of a
39
40 multiplex tie, actor A might occupy an institutionally defined role that gives it privileges over B;
41
42 yet in another domain B might have a role (or simply have higher bargaining power) than gives it
43
44 privileges over A. In our study, we controlled for the economic differences of the chaebols –
45
46 which might generate non-cultural, economic deference relationships in a business tie – through
47
48 the event study design coupled with matching and instrumental variable estimation. However,
49
50 future research could more directly examine the conditions under which deference pattern in one
51
52 domain of a multiplex tie could dominate another.
53
54
55
56
57
58
59
60

1
2
3 In conclusion, researchers recognize that many inter-organizational ties are multiplex, but
4
5 have frequently chosen not to examine the interdependences within multiplex relationships. We
6
7 agree that this approach was necessary when inter-organizational research was a young field of
8
9 study. Now we believe that research has progressed to the point in which ignoring multiplexity,
10
11 and the interdependences within the different domains of multiplex ties, impedes further progress.
12
13 Overlap of personal and business ties is omnipresent and infuses networks with multiple sources
14
15 of status, including some that stem from culture. By showing how a highly personal relation such
16
17 as marriage, combined with cultural norms, influences corporate market entry and exit we have
18
19 demonstrated that multiplex ties can have unique properties. This is just a starting point, however,
20
21 and we expect future research to uncover many other sources of multiplexity effects on inter-
22
23 organizational networks as well as interpersonal behaviors in organizations.

Total number of Observations	77956	2152	12378	532	58215	50604	9382	511

Note 1: The first number in each cell refers to the variable mean in control sample (i.e. firm-market-year observations that involved chaebols that did not form a marriage tie); the second number refers to the variable mean in the treatment sample (i.e. firm-market-year observations that involved chaebols which formed a marriage tie). Numbers in parentheses below these numbers represent standard deviations for control and treatment sample respectively.

Note 2: Significance levels (***) p<0.001, ** p<0.01, * p<0.05,+ p<0.1) are for the corresponding differences in means

Controls from Table 3	entered	entered	entered	entered
<i>Husband and Wife Chaebol</i>	Model 1a. Husband's Chaebol Entries (Dataset 1)	Model 1b. Husband's Chaebol Exits (Dataset 2)	Model 2a. Wives' Chaebol Entries (Dataset 3)	Model 2b. Wife's Chaebol Exits (Dataset 4)
<i>After Marriage</i>	0.293** (0.106)	0.747* (0.363)	-0.658** (0.166)	-0.588** (0.199)
Controls from Table 3	entered	entered	entered	entered

** p<0.01, * p<0.05, + p<0.10. Robust standard errors in parentheses. This table is a result of seemingly unrelated estimation pooling the analyses of the determinants of entries and exits done by the husbands' and the wives' chaebols. This technique combines estimation results -- parameter estimates and associated covariance matrices -- from the regressions to account for possible non-independence of entry and exit decisions made by the husbands' and wives' chaebols.

Table 6: Performance Consequences of Entries and Exits

	Model 1 (OLS)	Model 2 (OLS)	Model 3 (OLS)	Model 4 (Ordered Probit)
<i>Husband's Chaebol</i>		30.303+ (17.009)	28.970+ (16.004)	6.610** (2.245)
<i>Market Entries (Partner)</i>	4.625 (9.693)	16.054 (12.048)	15.582 (11.728)	1.779+ (0.930)
<i>Husband's Chaebol x Market Entries(Partner)</i>		-27.623+ (13.270)	-26.581+ (13.031)	-4.890** (1.599)
<i>Market Exits(Partner)</i>	-16.785 (20.449)	-15.647 (17.888)	-20.792 (29.308)	1.250 (1.482)
<i>Husband's Chaebol x Market Exits(Partner)</i>			8.478 (27.928)	-0.401 (1.291)
<i>Asset Size</i>	-5.756 (9.209)	-6.170 (7.950)	-6.093 (7.999)	0.384 (2.064)
<i>Specialization</i>	-21.052 (16.094)	-20.075 (14.414)	-19.015 (14.102)	-4.991** (1.932)
<i>Debt Load</i>	-5.077 (5.449)	-3.794 (5.582)	-3.185 (5.954)	0.157 (0.433)
<i>Profitability</i>	-5.534 (7.003)	-5.017 (7.120)	-5.499 (7.212)	0.733 (1.113)
<i>Alliances in Entered Markets</i>	-1.485 (3.353)	-0.693 (3.175)	-0.061 (4.218)	0.594 (1.215)
<i>Alliances in Exited Markets</i>	2.818 (2.272)	1.488 (2.016)	1.680 (2.357)	-0.046 (0.411)
<i>School Ties in Entered Markets</i>	-1.392 (1.236)	-1.818 (1.459)	-2.015 (1.820)	0.130 (0.738)
<i>School Ties in Existed Markets</i>	1.521 (4.038)	-4.199 (5.862)	-3.513 (6.572)	-0.830* (0.389)
<i>Competition in Entered Markets</i>	137.095 (92.986)	131.996 (91.351)	135.674 (96.594)	40.735** (11.641)
<i>Competition in Exited Markets</i>	-3.055 (10.427)	7.144 (16.023)	6.752 (16.698)	1.799 (1.199)
<i>Entry Ratio</i>	-104.833 (126.235)	-141.574 (119.764)	-141.511 (120.882)	-29.640* (13.761)
<i>Exit Ratio</i>	-149.009+ (77.461)	-207.238* (86.168)	-198.361* (89.871)	-51.262** (12.681)
<i>Market Entries (Other)</i>	9.240 (6.463)	8.597 (6.075)	8.669 (6.099)	0.871+ (0.479)
<i>Market Exits (Other)</i>	11.747 (8.527)	9.010 (9.090)	9.184 (9.357)	1.173 (0.845)
Constant	211.121 (374.614)	212.170 (332.171)	205.867 (337.771)	
Observations	153	153	153	153
R-squared	0.837	0.847	0.847	
Year dummies	Yes	Yes	Yes	Yes

** p<0.01, * p<0.05, + p<0.10. Robust standard errors in parentheses. In Model 4, there are multiple intercepts (cuts) for the ordered probit model as a function of the number of individual values in the dependent variable.

2
3 **JungYun Han** (jungyunhan@ntu.edu.tw) is an Assistant Professor of Management at National
4 Taiwan University. She received her Ph.D. from INSEAD. In her research, she examines how
5 inter-personal ties across organizations affect organizational behaviors and performance,
6 focusing on kinship ties.
7

8
9 **Andrew V. Shipilov** (andrew.shipilov@insead.edu) is a Professor and Akzo Nobel Fellow of
10 Strategic Management at INSEAD. He received his PhD from the Joseph L. Rotman School of
11 Management, University of Toronto. His research examines how social networks, strategic
12 alliances, and partnerships evolve and affect competitive advantage
13

14 **Henrich R. Greve** (henrich.greve@insead.edu) is a Professor of Entrepreneurship at INSEAD
15 and the John H. Loudon Chaired Professor of International Management. He received his Ph.D.
16 from Stanford University's Graduate School of Business. His current research is on organization-
17 community relations, organizational performance and aspiration levels, and organizational
18 adaptation to institutional environments.
